Doc: EVA-2.9-TST-CE7-ATOM

Issue: v2.1 on 6-Jun-2012

1 Document Intention

1.1 Purpose and scope

This document presents the quantitative evaluation results of the **Windows Embedded Compact7** OS on ATOM-based platform.

The layout of this report follows the one depicted in "The OS evaluation template" [Doc. 4]. The test specifications can be found in "The evaluation test report definition" [Doc. 3]. For more detailed references, See section "Related documents" of this document. These documents have to be seen as an integral part of this report!

Due to the tightly coupling between these documents, the framework version of "The evaluation test report definition" has to match the framework version of this evaluation report (which is 2.9). More information about the documents and tests versions together with their corresponding relation between both can be found in "The evaluation framework", see [Doc. 1] in section "Related documents" of this document.

The generic test code used to perform these tests can be downloaded on our website by using the link in the "related documents" section.

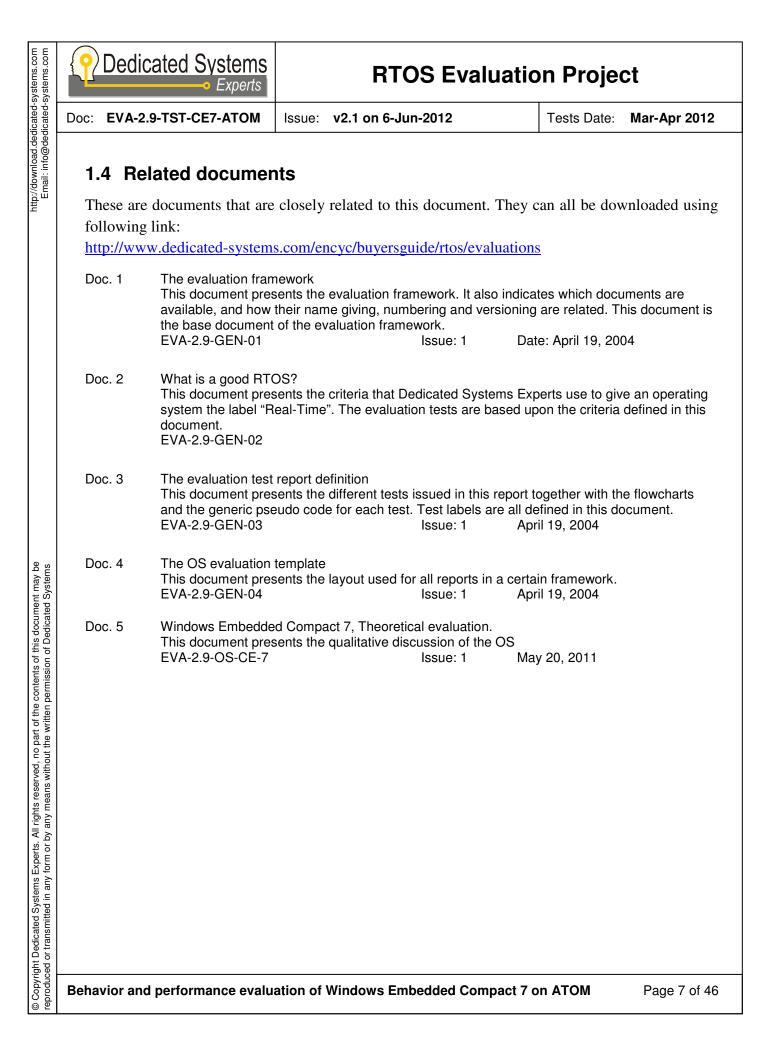

1.2 Test framework used: 2.9

This document shows the test results in the scope of the evaluation framework 2.9. More details about this framework are found in Doc 1 (see section "Related documents").

1.3 Conventions

Throughout this document, we use certain typographical conventions to distinguish technical terms. Our used conventions are the following:

- * Bold Italic for OS Objects
- * Bold for Libraries, packets, directories, software, OSs...
- ✤ Courier New for system calls (APIs...)

Doc: EVA-2.9-TST-CE7-ATOM

Issue: v2.1 on 6-Jun-2012

Tests Date: Mar-Apr 2012

2 Introduction

This chapter talks about the OS that we are going to test and evaluate, and the hardware on which the under testing OS will be employed to be tested.

2.1 Overview

Releasing a new OS with a different name (changed from **Windows CE** to **Windows Embedded Compact 7**) does not mean that we are up with a new OS! Such naming change was mainly done for marketing purposes, as there were no fundamental changes in the OS itself!

Further in the document, the full name "Windows Embedded Compact 7" or the short names "Compact 7" and "CE7" will be used.

2.2 Evaluated (RTOS) Product

This section describes the OS that Dedicated Systems tested using their Evaluation Testing Suite, and the hardware on which this OS was running during the testing.

2.2.1 Software

The RTOS that will be evaluated and tested is **Windows Embedded Compact 7**. This OS was launched by Microsoft Corporation at the beginning of 2011. In fact, this OS "**Windows Embedded Compact**" is the successor of **Windows CE6R3**.

The tests for evaluating this OS were done in March 2012.

2.2.2 Hardware

We tested the **Windows Embedded Compact 7** on an ATOM-based platform. This platform has the following characteristics:

Motherboard: Advantech SOM-6760, PCI bus at 33MHz, using the System Controller Hub US15W.

CPU: Intel Atom Z530 1.6GHz 133MHz Front Side Bus.

- 32KByte L1 Instruction Cache,
- 24KByte L1 Write Back Data Cache,
- 512KByte 8-way L2 Cache (which can be reduced up to zero in some processor sleep states)
- 1 core with hyper-threading support (however hyper threading was disabled during this test).
- RAM: 512MB DDR2
- VMETRO PCI exerciser in PCI slot 3 (PCI interrupt level D, local bus interrupt level 10)
- VMETRO PBT-315 PCI analyser in PCI slot 4.
- External and CPU internal cache was enabled during the tests.

EVA-2.9-TST-CE7-ATOM Doc:

Issue: v2.1 on 6-Jun-2012 Tests Date: Mar-Apr 2012

3 Evaluation results summary

Following is a summary of the results of evaluating Windows Embedded Compact 7, released by Microsoft Corporation, Inc.

3.1 Positive points

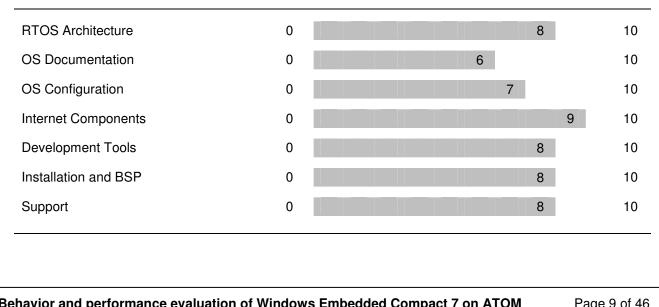

- 1) All protection primitives use priority inheritance, which is a major plus for achieving realtime behavior
- 2) Good debugging tools: Available also for kernel/driver debugging.
- 3) Very easy to install and to set-up a target (from templates).
- 4) Provides the same flexibility as a 32-bit general purpose OS

3.2 Negative points (see Microsoft's comments in section 3.4)

- 1) The operating system documentation has taken a step backwards compared with the previous versions. A lot of background information is removed (see MS comments).
- 2) Customizing the kernel and adding custom drivers (BSP) stays a daunting task once you go away from the default configurations.
- 3) The remote tool has been changed since last version. We noticed two issues, the more important of which is that there is no officially-supported method to include the remote tools within a device image using Platform Builder. Additionally, we noticed during our testing that establishing a connection between the tools and the target took in excess of a minute, which was longer than our expectation (see MS comments).

3.3 Ratings

For a description of the ratings, see [Doc. 3].

Behavior and performance evaluation of Windows Embedded Compact 7 on ATOM

Page 9 of 46

Doc: EVA-2.9-TST-CE7-ATOM

Issue: v2.1 on 6-Jun-2012

3.4 Vendor Comments

Following are the comments of Microsoft on the negative points:

- **For point 1** Microsoft notes that documentation is a focus for the next release, and the product team plans to bring forward any relevant content from earlier releases, which will be identified as still applicable to the current release.
- **For point 3** Microsoft notes that the ability to add the remote tools to a device image using Platform Builder is by design, as generally a finished device's final image would not normally include debug support. Additionally, because some devices won't have a .CAB installer, making installation of the remote tools a challenge. They are investigating now how to provide this support in a future release of Platform Builder. Microsoft also notes that the Compact Product Team was unable to reproduce the delayed connection time experienced by Dedicated Systems but will continue to investigate whether connection time is a persistent issue.

4 Test Results			
Test Results	0	8 10	
As usual. Compact 7 real-time be	abavior is excellent		

4.1 Calibration system test (CAL)

"Calibration tests" are performed to calibrate the tracing overhead compared with the processing power of the platform. Such tests are important to understand the accuracy of the measurements done in scope of this report, and for measuring the processing power of the platform. This calibration permits comparison with the results on other platforms.

4.1.1 Tracing overhead (CAL-P-TRC)

On this board we used the PCI analyzer as a mechanism to measure event durations.

"Tracing overhead test" calibrates the tracing system overhead. It is more related to the hardware than the OS because its aim is to correct the measured time values.

In the rest of the document, the tracing overhead is subtracted from the obtained results.

In general, the results in this report are correct to $\pm - 0.2 \mu$ seconds. Therefore the results shown in the tables are rounded to 0.1 microseconds.

4.1.1.1 Test results

Test	result
Average tracing overhead	271 nsec
minimum tracing overhead	271 nsec
maximum tracing overhead	271 nsec

Doc: EVA-2.9-TST-CE7-ATOM

Issue: v2.1 on 6-Jun-2012

4.1.2 CPU power (CAL-P-CPU)

The "CPU power" test calibrates the CPU performance and the memory bandwidth of the used platform. This test is measured in different situations, starting from the situation where code and data are cached, until the situation where neither code nor data are cached. With such different situation tests, the effects of the cache can be calculated.

We have been seriously reworking this test lately. The CPU test uses only one data address; The non-cached version is about 128KB in size (instructions), while the cached version uses a loop (a bit unrolled to have a small loop overhead but so it fits in the L1 I-cache and it uses only two data words). The instruction cache test is done twice:

- The instructions have not been mapped yet (leading to TLB exceptions and page faults)
- There will not be any page faults (TLB exceptions will still happen).

This gives us some indication about the impact of page faults.

For this specific ATOM platform, we used a factor 5 for the test, so that $5 \ge 128$ KB = 640KB is larger than the L1/L2 caches. After the test, we divide the results by 5, in order to be capable to compare the results with other platforms

Further, we divided the data cache tests into a read test (reading content of a large array in noncached case, and read a small array in a loop in the cached case) and a write test. Remark that we flush the caches in between the tests.

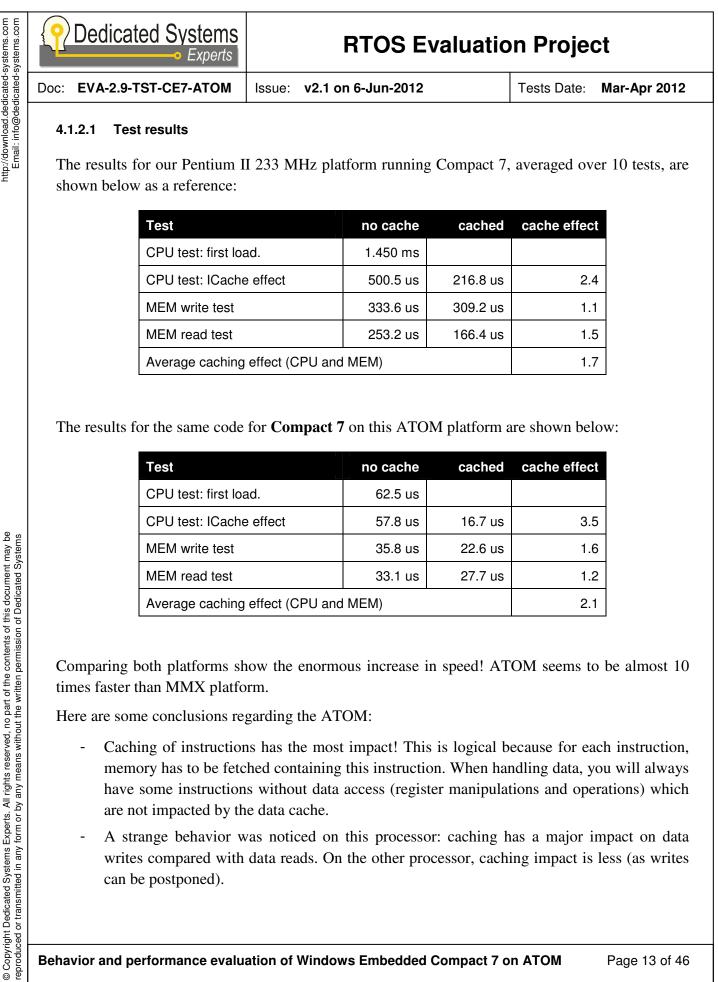

This rework shows that a worst-case / best-case scenario can cause significant performance impacts, something that in reality will almost surely never be that large (or you should be able to run everything using only L1 caches).

The impact of either having the code in the I-Cache or not, has serious effect on the results of the tests.

Remark that the results of such tests will depend also, to a high extent, on the cache organization:

- Number of ways
- Line size
- Number of address bits used for index
- Virtual or physical addresses used as index.

A strange behavior was noticed on this processor: caching has a major impact on data writes compared with data reads. On the other processor, caching impact is less (as writes can be postponed).

 Producted Systems
 RTOS Evaluation Project

 Doc:
 Experts

 Doc:
 EVA-2.9-TST-CE7-ATOM

 Issue:
 v2.1 on 6-Jun-2012

 Tests Date:
 Mar-Apr 2012

- In general, this platform is less impacted by cache misses compared with, for instance, the ARM Beagle platform. It seems that the RAM speed is still adequate compared with the caches.

The results cannot be completely compared with other tests that we did on the same platform. Even if the same code is used, these figures can be different depending on compiler optimizations and compiler versions.

4.2 Clock tests (CLK)

"Clock tests" measure the time needed by the operating system to handle its clock interrupt. On the tested platform, the clock tick interrupt is set on the highest hardware interrupt level, interrupting any other thread or interrupt handler.

4.2.1 Operating system clock setting (CLK-B-CFG)

The "OS clock setting" test examines the setting of the clock tick period in the operating system. This test shows the default clock timing as they are set by the BSP and/ or the kernel.

Remark that in Compact 7, when performing a sleep(0), the call will immediately return (if no other threads are running at the same priority level). Other sleeps behave normal. Microsoft provides a SleepTillTick() call for this purpose:

Thus in practice:

- Sleep(0) will not sleep, but will yield if there is another thread of same priority runnable.
- SleepTillTick() will sleep between 0-1 ms.
- Sleep(n) will sleep between n and (n-1) ms.

4.2.1.1 Test results

Test	result
Test succeeded	Yes (SleepTillTick)
Tested clock period	1ms
Clock period adaptable	NO

Doc: EVA-2.9-TST-CE7-ATOM

Issue: v2.1 on 6-Jun-2012

4.2.2 Clock tick processing duration (CLK-P-DUR)

The "clock tick processing duration" test examines the clock tick processing duration in the kernel. The test results are extremely important, as the clock interrupt will disturb all the other performed measurements.

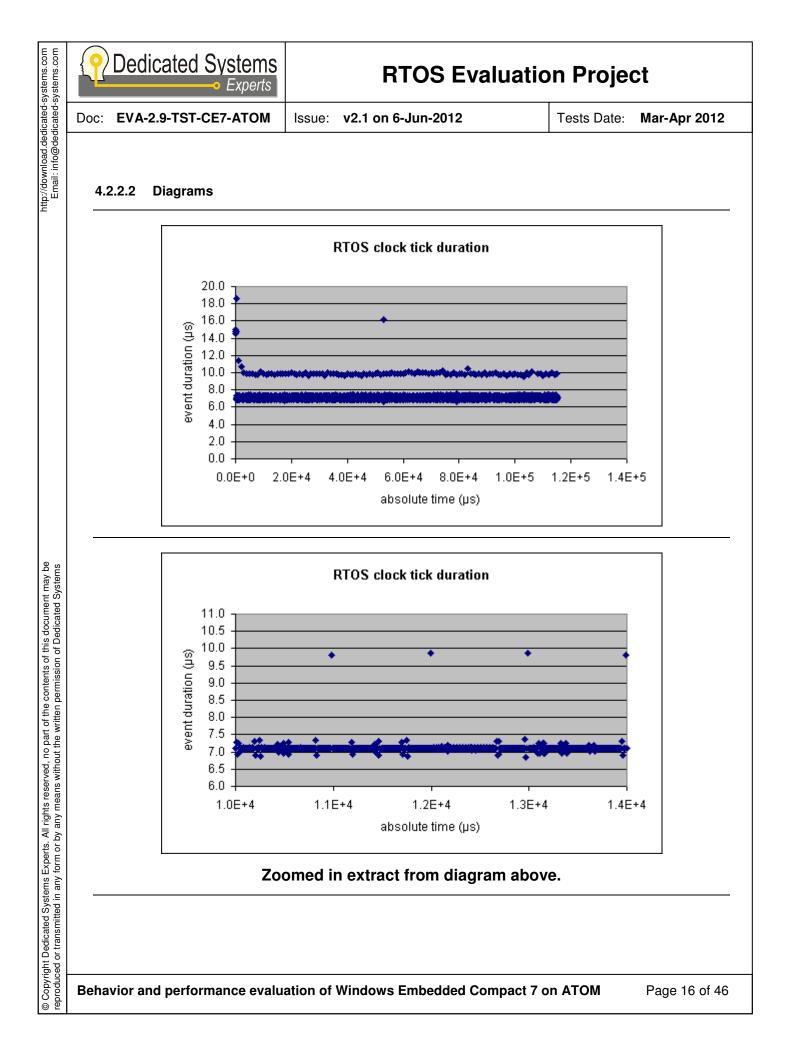

The bottom line of the figures in section 4.2.2.2 represents the normal loop time of the test if no clock interrupt occurs during the test loop. The upper line is generated by the samples when a clock interrupt occurred during the loop. The difference between the two lines is the clock tick processing duration.

Be careful: the OAL layer may stop the clock tick interrupt if not needed (tickles kernel). However, this will happen only if the CPU load is minimal, in which case the used memory bandwidth will be small.

Even that an ATOM is much faster than our standard Pentium MMX 200MHz evaluation platform, interrupt latency is not that much better. A part of the interrupt latency is also hardware dependent and thus not only dependent on CPU speed.

Test	result
CLOCK_LOOP_COUNTER	1000
Normal busy loop time	7.0 μs
Busy loop time with clock interrupt	10 μs, worst case 19 μs
Clock interrupt duration	3 μs to 12 us

4.2.2.1 Test results

Doc: EVA-2.9-TST-CE7-ATOM

Issue: v2.1 on 6-Jun-2012

4.3 Thread tests (THR)

"Thread tests" measure the scheduler performance.

4.3.1 Thread creation behaviour (THR-B-NEW)

The "thread creation behavior" test examines the OS behavior when it creates threads. This test attempts to answer the question: Does the OS behave as it should in order to be considered a real-time operating system? Following scenarios are tested:

- If a thread is created with a lower priority than the creating thread, then are we sure that it is not activated until the creating thread is finished?
- If a thread is created with the same priority as the creating thread, will it be placed at the ready tail?
- When yielding after the creation in the above test, does the newly created thread becomes active?
- If a thread is created with a higher priority than the creating thread, is it then immediately activated?

This test succeeded without any problems.

4.3.1.1 Test results

Test	result
Test succeeded	YES
Lower priority not activated?	YES
Same priority at tail?	YES
Yielding works?	YES
Higher priority activated?	YES

P Dedicated Systems

RTOS Evaluation Project

Doc: EVA-2.9-TST-CE7-ATOM

Issue: v2.1 on 6-Jun-2012

Tests Date: Mar-Apr 2012

4.3.2 Round robin behaviour (THR-B-RR)

The "round robin behavior" test checks if the scheduler uses a fair round robin mechanism to schedule threads that use the round robin scheduling policy, are of the same priority, and are in the ready-to-run state!

O A problem was detected here: the first time a thread becomes active, it takes a longer time slice (100ms) than in the other cases (1ms = clock tick).

We took a look back to the test results of **CE 6.0** and discovered that the same problem was indeed present there as well. To be sure that we didn't do anything wrong in the test, we compared the code for this test with the test code of other RTOS which did not have this behavior and no differences were found.

The problem is caused by the fact that the default round robin time slice for a thread used in CE 7.0 is 100ms. When adapting the time slice to 1ms, then this will only have impact on the next scheduling round. Even if you set the time slice before starting the thread (suspended mode) it will only be applied on the next end of the time slice.

Although it is strange behavior, creating dynamically threads in a real-time system is a bad practice which is normally never done. As such, this problem will not have any impacts in real use cases.

TestresultTest succeededNo (first time slice after thread creation is longer)RR Time slice following this test1 clock tick normally (first slice takes 100 clock ticks)

4.3.2.1 Test results

4.3.3 Thread switch latency between same priority threads (THR-P-SLS)

The "thread switch latency between same priority threads" test measures the time needed to switch between threads of the same priority. For this test, threads must voluntarily yield the processor for other threads.

This test was performed in order to generate the worst-case behavior. We performed the test with an increasing number of threads, starting with two (2) and going up to 1000 in order to observe the behavior in a worst-case scenario. As we increase the number of active threads, the caching effect becomes evident since the thread context will no longer be able to reside in the cache (on this platform the L1 caches are 32KB, for the instruction cache and 28KB for the data cache).

Pedicated Systems	RTOS Evaluatio	on Project
Doc: EVA-2.9-TST-CE7-ATOM	Issue: v2.1 on 6-Jun-2012	Tests Date: Mar-Apr 2012

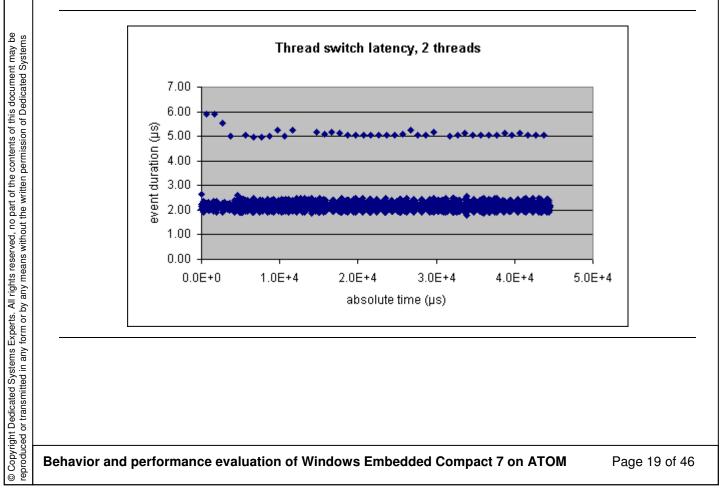

As the L2 cache is much larger, 512KB, it is not likely that the clock tick will not be located in this cache anymore.

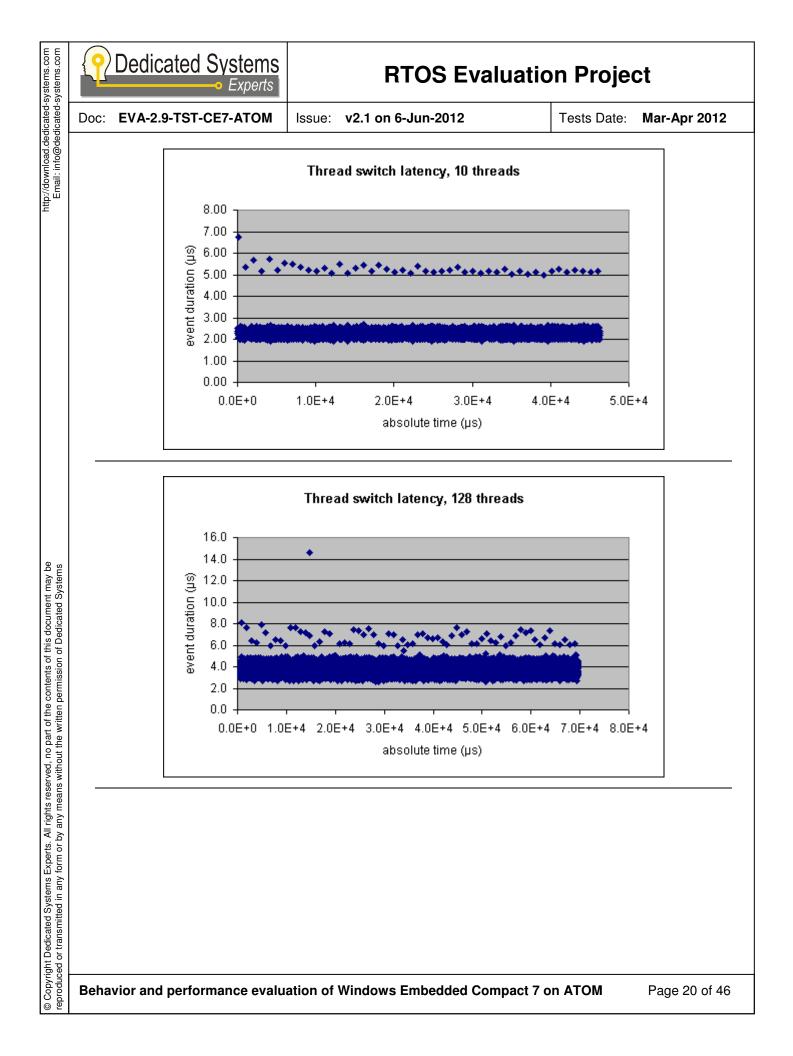

4.3.3.1 Test results

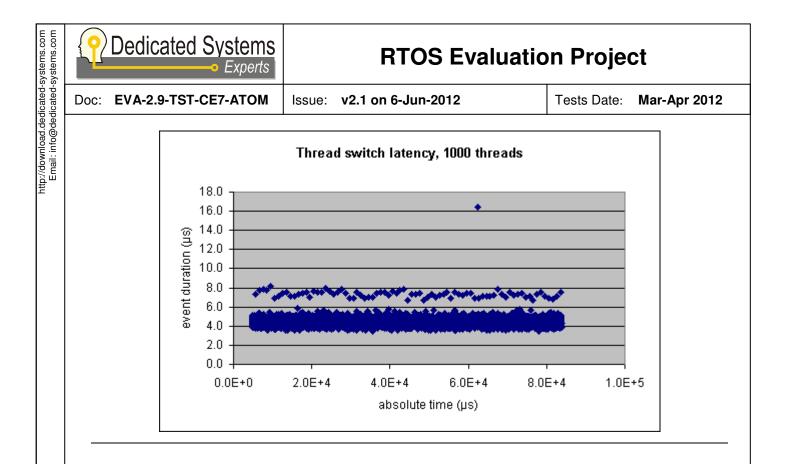

Test	result
Test succeeded	YES

Test	Sample qty	Avg	Max	Min
Thread switch latency, 2 threads	16383	2.1 μs	5.9 µs	1.8 µs
Thread switch latency, 10 threads	16383	2.3 µs	6.7 μs	1.9 µs
Thread switch latency, 128 threads	16320	3.7 μs	14.6 µs	2.6 µs
Thread switch latency, 1000 threads	16383	4.4 μs	16.4 µs	3.5 µs

4.3.3.2 Diagrams

4.3.4 Thread creation and deletion time (THR-P-NEW)

The "thread creation and deletion time" test examines the time required to create a thread, and the time required to delete a thread in the following different scenarios:

- Scenario 1 "never run": The created thread has a lower priority than the creating thread and is deleted before it has any chance to run. No thread switch occurs in this test.
- Scenario 2 "run and terminate": The created thread has a higher priority than the creating thread and will be activated. The created thread immediately terminates itself (thread does nothing).
- Scenario 3 "run and block": The same as the previous scenario (scenario 2: run and terminate), but the created thread does not terminate (it lowers its priority when it is activated).

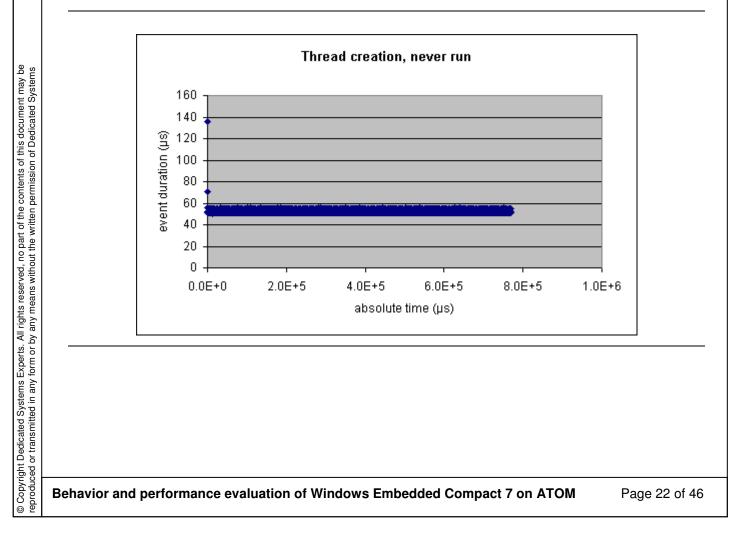

In the scenarios where the thread actually runs (2 and 3), the creation time is measured as the duration from the system call creating the thread until the time when the created thread is activated. For the "never run" scenario, the creation time is measured as the duration of the system call.

In this test we see clearly the impact of the caches: the first time everything has to be retrieved from RAM (large number of instructions which are not cached, this combined with some data) and as a result, the first measured event takes more than twice the time than the subsequent events.

4.4 Semaphore tests (SEM)

"Semaphore tests" examine the behavior and performance of the OS counting semaphore. The counting semaphore is a system object that can be used to synchronize threads.

4.4.1 Semaphore locking test mechanism (SEM-B-LCK)

In this test, we verify if the counting semaphore locking mechanism works as it is expected to work. If this mechanism works as expected, then:

- The P () call will block only when the count is zero.
- The V () call will increment the semaphore counter.
- In the case where the semaphore counter is zero, the V () call will cause a rescheduling by the OS, and blocked threads may become active.

The semaphore behaves correctly as a protection mechanism.

4.4.1.1 Test results

Test	result
Test succeeded	YES
Maximum semaphore value?	Limited by the "int" type
Rescheduling on free?	ОК

Doc: EVA-2.9-TST-CE7-ATOM

Issue: v2.1 on 6-Jun-2012

Tests Date: Mar-Apr 2012

4.4.2 Semaphore releasing mechanism (SEM-B-REL)

The "semaphore releasing mechanism" test verifies that the highest priority thread being blocked on a semaphore will be released by the release operation. This action should be independent of the order of the acquisitions taking place.

Windows Embedded Compact 7 passed this test.

4.4.2.1 Test results

Test	result
Test succeeded	YES

4.4.3 Time needed to create and delete a semaphore (SEM-P-NEW)

The "time needed to create and delete a semaphore" test is performed to gain an insight about the time needed to create a semaphore and the time needed to delete it. The deletion time is checked in two cases:

- The *semaphore* is used between the creation and deletion.
- The *semaphore* is NOT used between the creation and deletion.

Remark that although we do not use "named" *semaphores*, there seems to be a system call required to create/delete a semaphore.

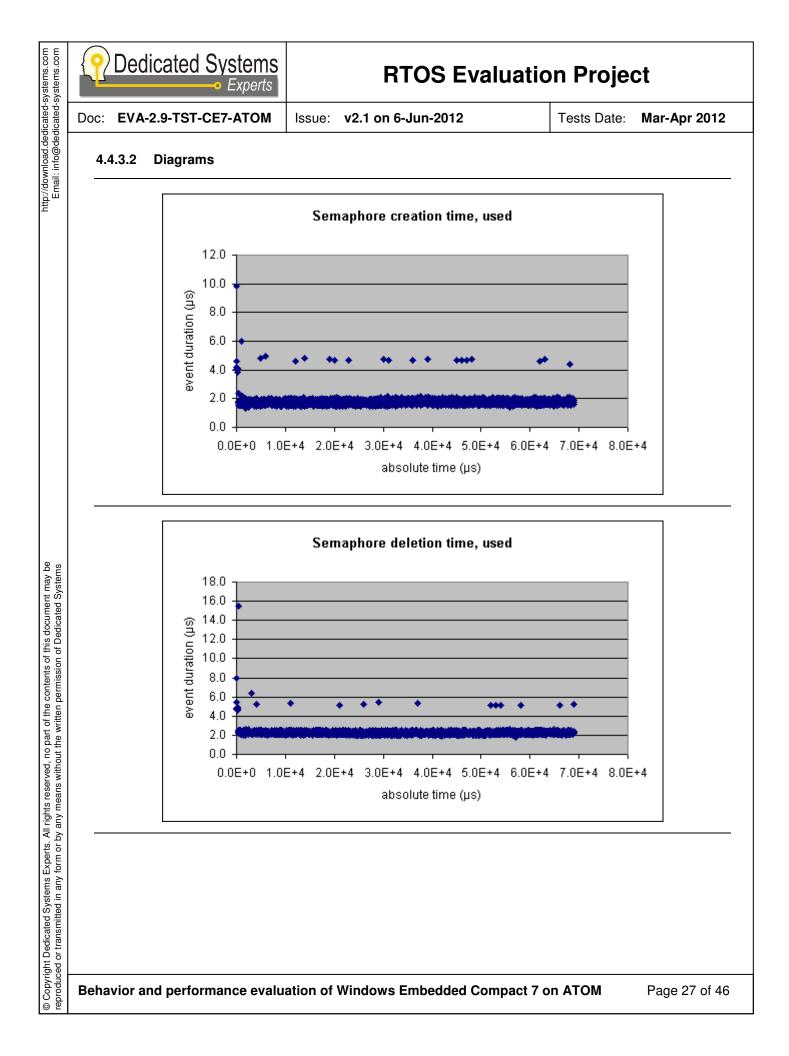

The clock tick line is clearly visible.

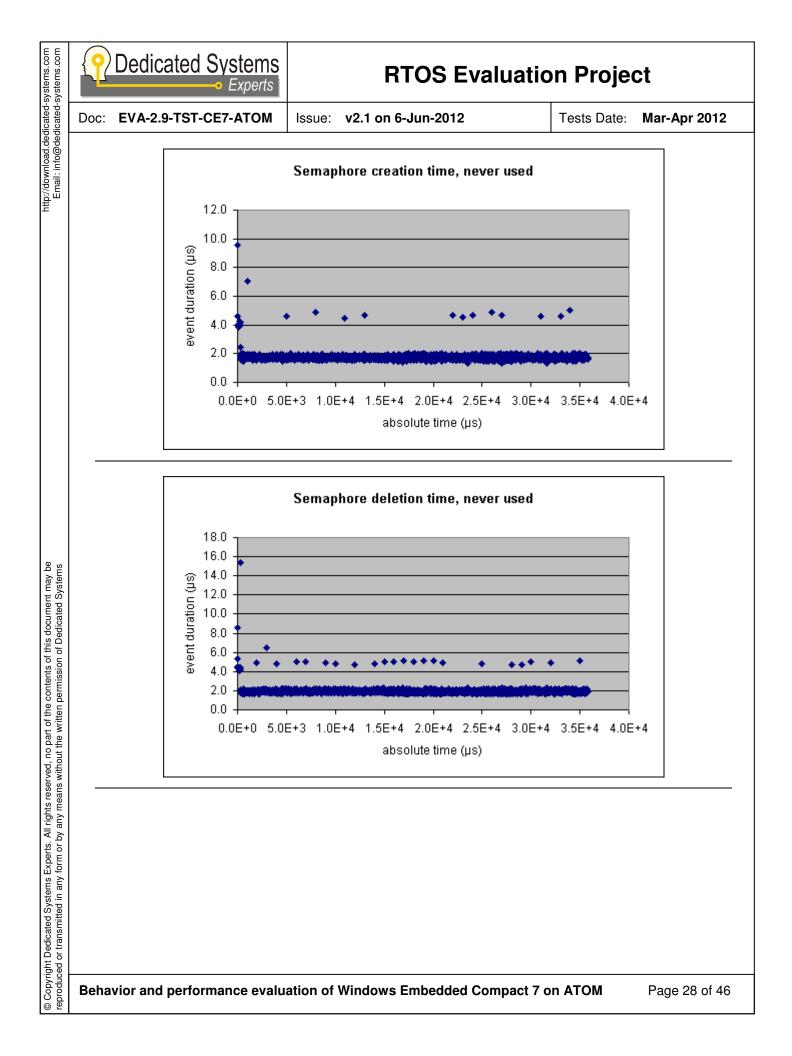

4.4.3.1 Test results

Test	result
Test succeeded	YES

Test	Sample qty	Avg	Max	Min
Semaphore creation time, used	7500	1.8 µs	9.8 µs	1.4 μs
Semaphore deletion time, used	7500	2.3 µs	15.5 μs	1.8 µs
Semaphore creation time, never used	7500	1.7 μs	9.5 µs	1.3 µs
Semaphore deletion time, never used	7500	2.0 μs	15.4 μs	1.6 µs

Doc: EVA-2.9-TST-CE7-ATOM

Issue: v2.1 on 6-Jun-2012

Tests Date: Mar-Apr 2012

4.4.4 Test acquire-release timings: non-contention case (SEM-P-ARN)

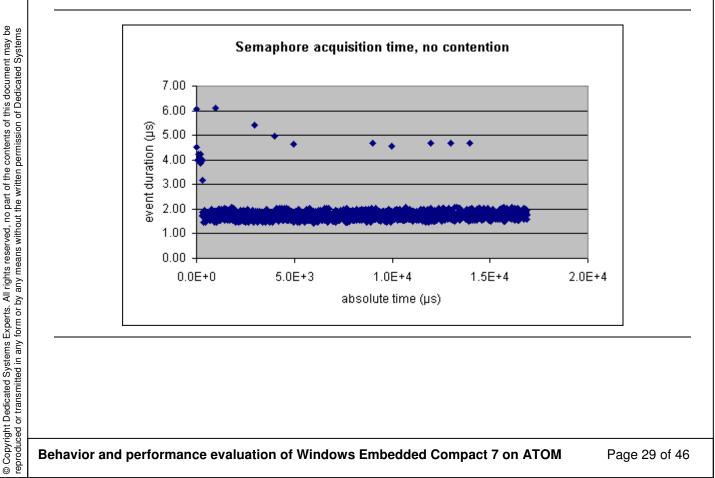

The "acquire-release timings: non-contention case" test measures the acquisition and release time in the non-contention case. Since in this test the semaphore does not neither block nor causes any rescheduling (thread switching), the duration of the call should be short.

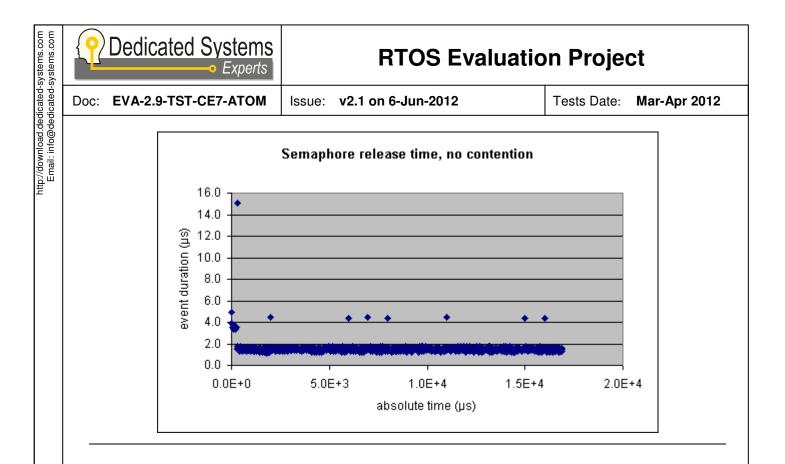

4.4.4.1 Test results

Test	result
Test succeeded	YES

Test	Sample qty	Avg	Max	Min
Semaphore acquisition time, no contention	3850	1.8 µs	6.1 μs	1.4 μs
Semaphore release time, no contention	3849	1.5 µs	15.1 μs	1.1 μs

4.4.4.2 Diagrams

4.4.5 Test acquire-release timings: contention case (SEM-P-ARC)

The "acquire release timings: contention case" test is performed to test the time needed to acquire and release a semaphore, depending on the number of threads blocked on the semaphore. It measures the time in the contention case when the acquisition and release system call causes a rescheduling to occur.

The purpose of this test is to see if the number of blocked threads has an impact on the times needed to acquire and release a semaphore. It attempts to answer the question: "How much time does the OS needs to find out which thread should be scheduled first?"

In this test, since each thread has a different priority, the question is how the OS handles these pending thread priorities on a semaphore. To have a more clear view on our test, you can take a look on the expanded diagrams during a small time frame (e.g. one test loop):

- We create 128 threads with different priorities. The creating thread has a lower priority than the threads being created.
- When the thread starts execution, it tries to acquire the *semaphore*; but as it is taken, the thread stops and the kernel switch back to the creating thread. The time from the acquisition attempt (which fails) to the moment the creating thread is activated again is called here the "acquisition time". Thus, this time includes the thread switch time.
- Thread creation takes some time, so the time between each measurement point is large compared with most other tests.

- After the last thread is created and is blocked on the *semaphore*, the creating thread starts _ to release the *semaphore* repeating this action the same number of times as the number of blocked threads on the semaphore.
- We start timing at the moment the *semaphore* is released which in turn will activate the pending thread with the highest priority, which will stop the timing (thus again the thread switch time is included).

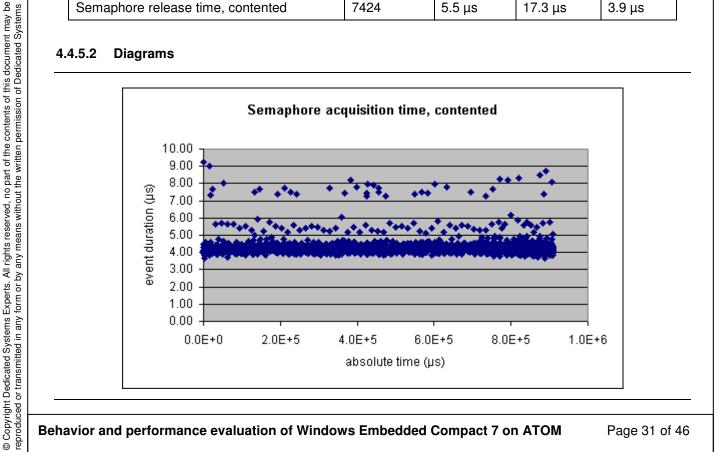

Now, the most important part of this test is to see if the number of threads pending on a semaphore has an impact on release times. Clearly, it doesn't, so this is good.

4.4.5.1 **Test results**

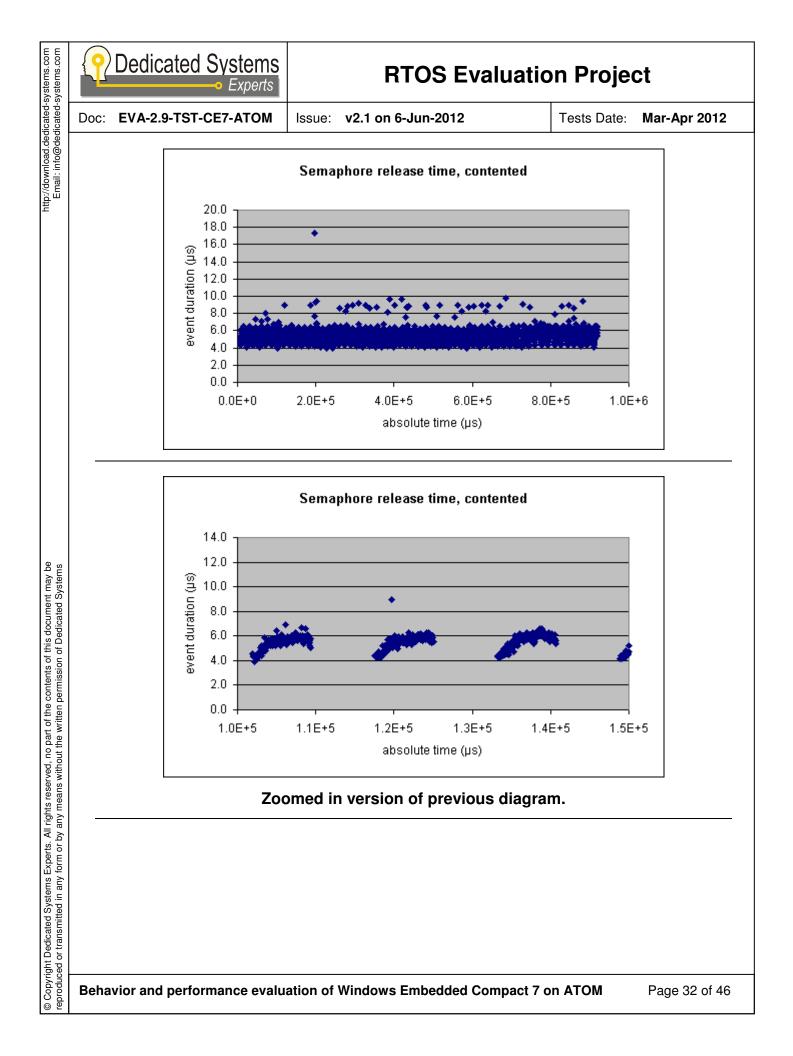

Test	result
Test succeeded	YES
Max number of threads pending	128

Test	Sample qty	Avg	Max	Min

4.5 Mutex tests (MUT)

Our "mutex tests" help us evaluate the behavior and performance of the mutual exclusive semaphore.

Although the mutual exclusive semaphore (further called mutex) is usually described as being the same as a counting semaphore where the count is one, this is not true. The behavior of a mutex is completely different than the behavior of a semaphore. Unlike semaphores, mutexes use the concept of a "lock owner", and can thus be used to prevent priority inversions. Semaphores cannot do this, and it goes without saying that mutexes (and not semaphores) should not be used semaphores for critical section protection mechanisms. In scope of the framework, this test will look into detail of a mutex system object that avoids priority inversion. The one used is the critical section one.

Remark that, Windows Embedded Compact 7 has as well a *Mutex* system object; but this should be used only between processes as it always requires a long round-trip to the kernel even if the lock is not contented.

Remark as well that there exists InterlockedXXX functions, which use the available CPU instruction set to provide atomic behavior and as a result, these are fast.

4.5.1 Priority inversion avoidance mechanism (MUT-B-ARC)

The "priority inversion avoidance mechanism" test determines if the system call being tested prevents the priority inversion case. To check this possibility, the test artificially creates a priority inversion.

The behavior test was performed using the Windows Embedded Compact 7 Critical section object.

The mutex object can be used between processes but therefore it requires of course each time a call to the kernel.

Therefore it is better to use the Critical Section object for protection between threads within a process. In this case, no kernel calls are needed if the lock is not contended, which increases a lot the speed of the lock under normal usage scenarios.

Priority inversion behaves as expected for both lock objects.

4.5.1.1 Test results

Test	result
Priority inversion avoidance system call present	Yes
System call used	InitializeCriticalSecton, EnterCriticalSection, LeaveCriticalSection.
Test succeeded	YES
Priority inversion avoided	YES
Mechanism used if any?	Priority inversion cannot be disabled in Compact 7 , which is a plus!

4.5.2 Mutex acquire-release timings: contention case (MUT-P-ARC)

The "mutex acquire-release timings: contention case" test is the same test as the "priority inversion avoidance mechanism" test described above, but performed in a loop. In this case, we measure the time needed to acquire and release the mutex in the priority inversion case.

Our test is designed so that the acquisition enforces a thread switch:

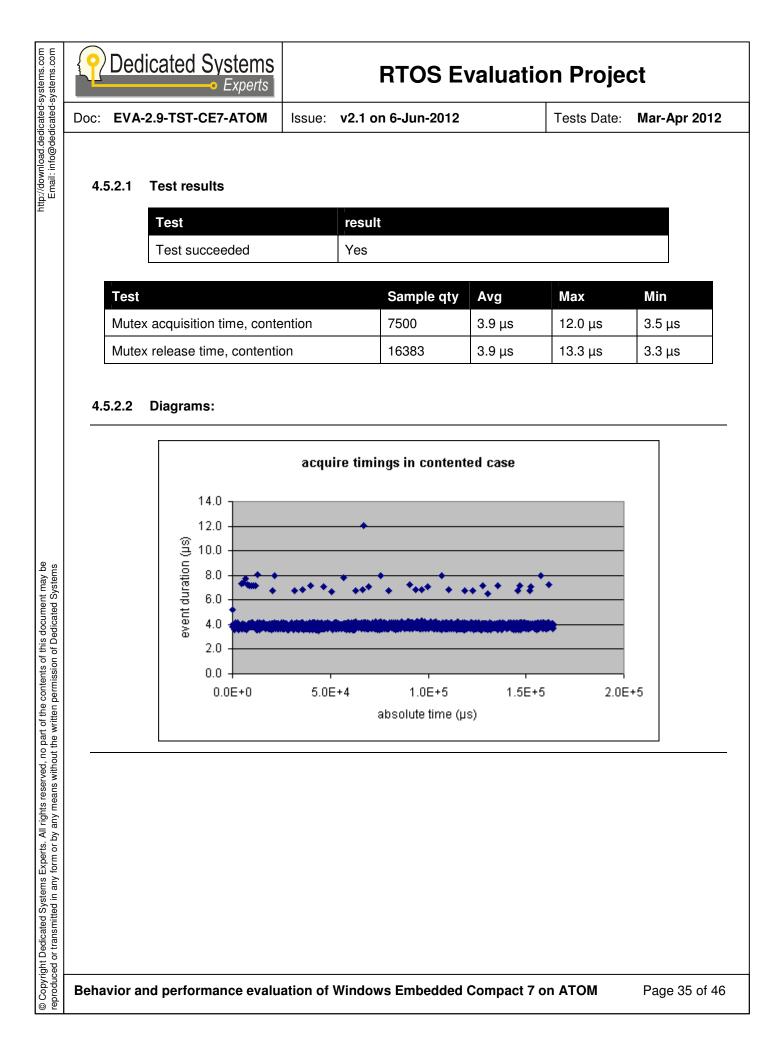

- The acquiring thread is blocked
- The thread with the lock is released.

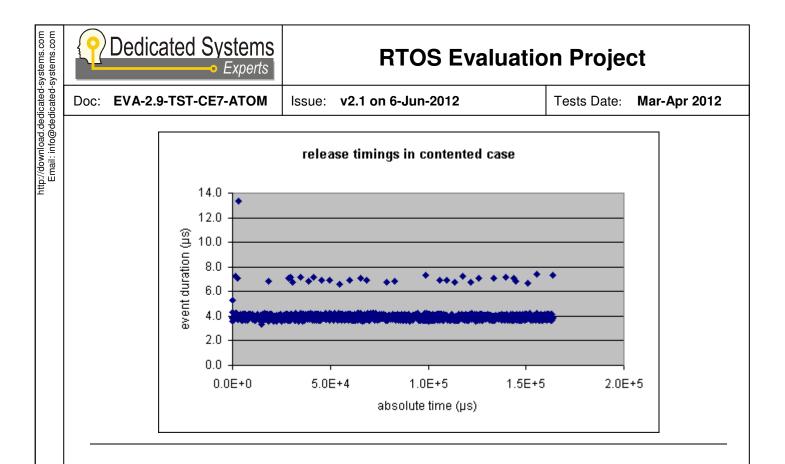

We measured the acquisition time from the request for the mutex acquisition to the activation of the lower priority thread with the lock.

Note that before the release, an intermediate priority level thread is activated (between the low priority one having the lock and the high priority one asking the lock). Due to the priority inheritance, this thread does not start to run (the low priority thread having the lock inherited the high priority of the thread asking the lock).

We measured the release time from the release call to the moment the thread requesting the mutex was activated; so this measurement also includes a thread switch.

The clock tick interrupt can be clearly seen (as usual) (figures of section 4.5.2.2).

4.5.3 Mutex acquire-release timings: non-contention case (MUT-P-ARN)

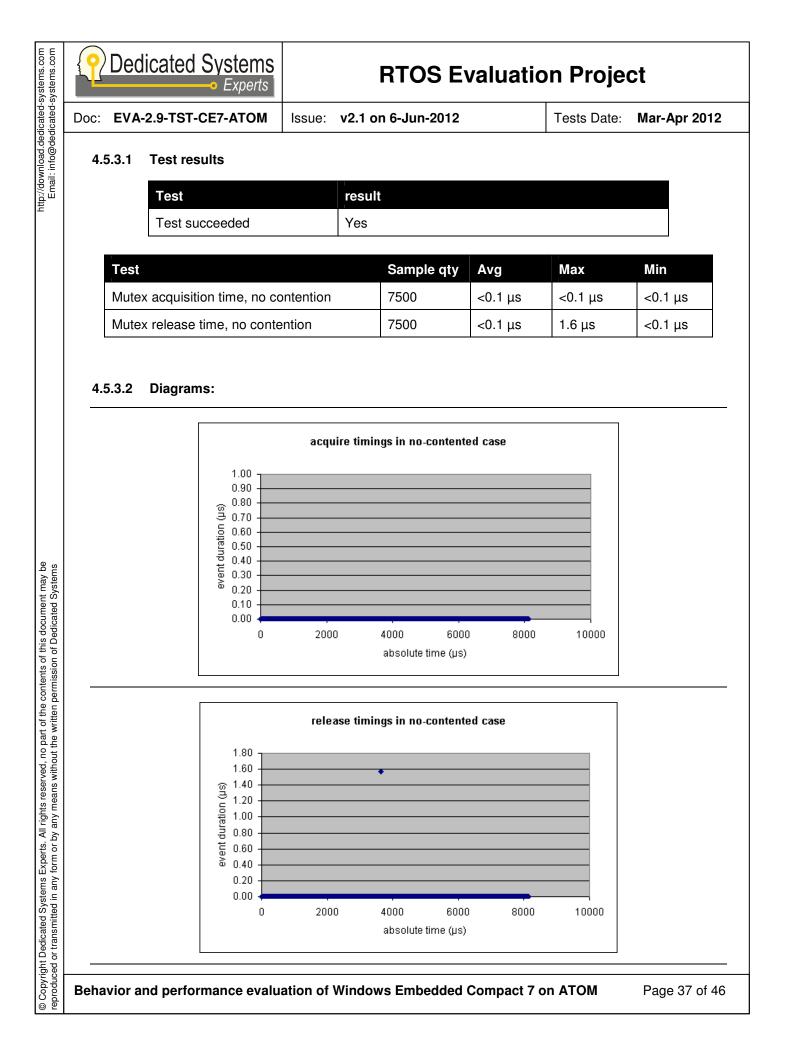

The "mutex acquire-release timings: no contention case" test measures the overhead incurred by using a lock when this lock is not owned by any other thread. Well-designed software will use non-contended locks most of the time, and only in some rare cases the lock will be taken by another thread.

Therefore, it is important that the non-contention case should be fast. Remark that this is only possible if:

- The CPU supports some type of atomic instruction, so that no system call is needed when no contention is detected.
- A lock is not shared between processes.

The last requirement is valid only when the Critical Section object in Compact 7 is used, because the Mutex object is an object meant to be used in a shared process scenario and does not contain this optimization.

Performance is excellent and too small to measure!

4.6 Interrupt tests (IRQ)

"Interrupt tests" evaluate how the operating system performs when handling interrupts.

Interrupt handling is a key system capability of real-time operating systems. Indeed, RTOSs are typically event driven.

For our interrupt tests, we use a PCI board to generate interrupts. The PCI board we used has an independent programmable interrupt generator, which protects it from influence by the RTOS clock. This protection allows us to guarantee that an independent interrupt source is not synchronized in any way with the platform being tested.

4.6.1 Interrupt latency (IRQ_P_LAT)

The "interrupt latency" test measures the time it takes to switch from the hardware interrupt to an interrupt handler. This time is measured from the moment the interrupt line on the PCI is toggled up to the instruction in the interrupt handler which clears the interrupt. Therefore the measurement does take into account the hardware interrupt latency as well.

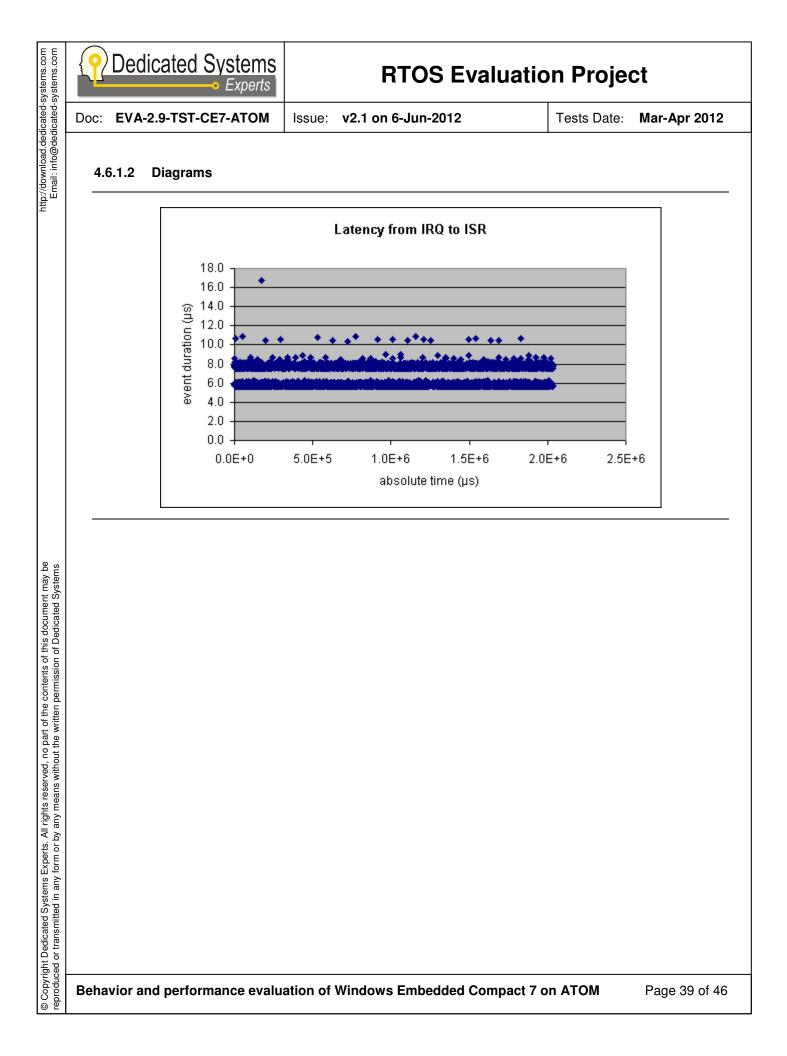

Remark that in Windows Embedded Compact 7, the interrupt handler is normally already a thread. However on this platform we added our own interrupt handler which is run in interrupt context and activates then the Interrupt Servicing Thread (IST).

The 2us between the two lines was caused by outstanding PCI transaction which has to be finished. This transaction takes 1.9μ s, so if the CPU wanted to jump to the interrupt context with an outstanding transaction then the context switch is still blocked for 1.9us which gives the extra delay. However this transaction gives us a good way to detect when the interrupt line was toggled. Anyhow, this impacts more the hardware latency than the latency introduced by the OS.

The clock time is easily detected again (it has the highest interrupt level).

4.6.1.1 Test results

Test	Sample qty	Avg	Max	Min
Latency from HW IRQ to ISR	8173	6.7 us	16.7 us	5.6 us

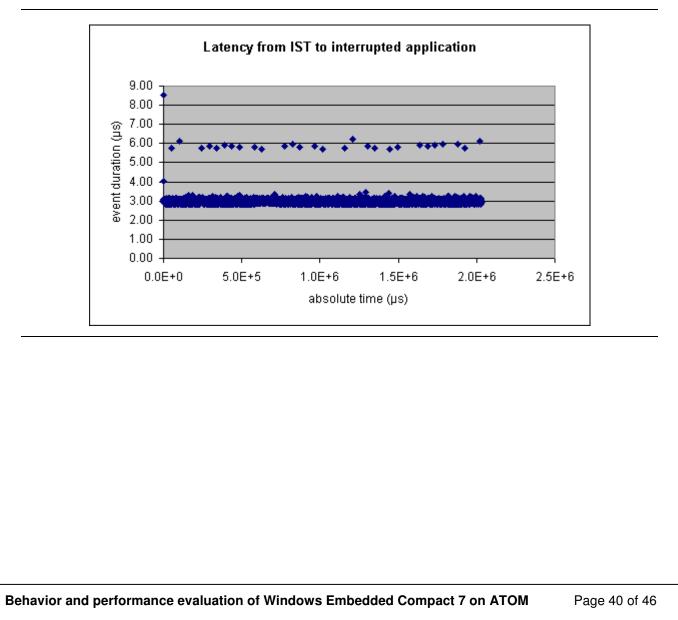

4.6.2 IST to interrupted thread latency (IRQ_P_DLT)

The "interrupt dispatch latency" test measures the time the OS takes to switch from the interrupt servicing thread (standard mechanism to handle interrupts in Windows CE) back to the interrupted thread.

4.6.2.1 **Test results**

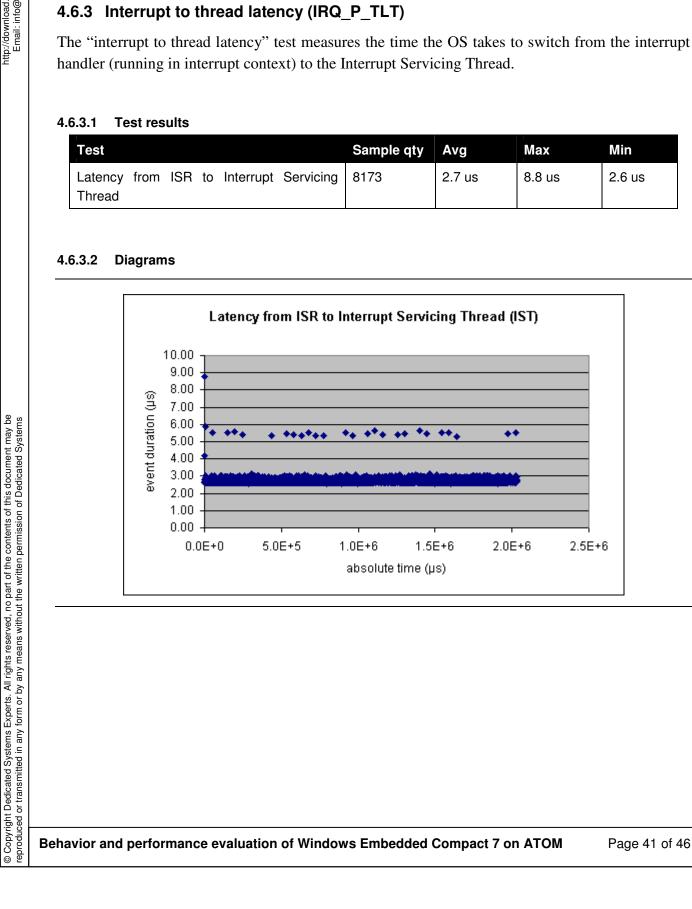

Test	Sample qty	Avg	Max	Min
Latency from IST to interrupted thread	8172	3.0 us	8.5 us	2.8 us

4.6.4 Maximum sustained interrupt frequency (IRQ_S_SUS)

The "maximum sustained interrupts frequency" test measures the probability that an interrupt might be missed. It attempts to answer the question: Is the interrupt handling duration stable and predictable?

Remark first that for this test, an interrupt service thread is used; so compared with other RTOS, extra context switch latency should be added (needed to be added twice in this case: interrupt start and interrupt leave).

We note that the rather long duration to handle the clock tick interrupt is due to the implementation by the BSP vendor, which in this case came from a 3rd party. We expect that improvements to the BSP would decrease the long duration.

This test is done in 3 phases:

- 1000 interrupts as an initial phase: a fast test just to see where we have to start searching.
- 1 000 000 interrupts as a second phase based on the results from the first phase. This test still takes less than a minute and gives already accurate results.
- 1 billion interrupts as a last phase, which takes few hours, and sometimes more than 24 hours, depending on the used platform and OS. This phase is done to verify stability; therefore, we cannot run this phase many times, especially when it comes to large interrupt latencies.

As one can observe in the above interrupt test results, the interrupt latency is 6.7 μ s in the best case. But due to the clock interrupt, the latency increases. For a long run, we need about 44 μ s not to miss one interrupt, as shown in the test results below.
